

***Muslim and Non-Muslim Differentials in Three Critical RCH Indicators in Muslim
Densely Populated States of India.***

“Whose faces are behind the numbers? What were their stories? What were their dreams? They left behind children and families. They also left behind clues as to why their lives ended early” (WHO, 1999).

The death of a woman during pregnancy and childbirth is not only a health issue but also a matter of social injustice. Pregnancy and child birth is a normal psychological process and every pregnant woman hopes to give birth safely. Sadly, this is not what is actually happening. Every minute a woman dies as a result of pregnancy or childbirth. In 2010, nearly 287,000 maternal deaths occurred worldwide, a down from 358,000 in 2008. Developing countries accounted for nearly 99% of this death and 25% global burden by India.

This study makes an attempt to explore association between maternal death and associated factors in West Bengal using the approaches of facility-based and community-based maternal death review. 110 deaths due to maternal related causes which took place during December, 2010 to June 2012 in Gynecology and Obstetrics department of Calcutta Medical College & Hospital (CMC) are reviewed. Special Bulletin on Maternal Mortality of Sample Registration System is also taken as secondary data and we have conducted 15 verbal autopsies in order to understand causes of deaths. Bivariate and binary logistic regression analysis has been performed to understand the causes and circumstances of maternal deaths in West Bengal. This study is useful in exploring the causes and planning & implementation of interventions so that most of the maternal deaths in West Bengal can be averted.

An overwhelming majority of the deaths (72%) are referral cases; most of such referrals had been from subdivision hospital/ rural hospital or community health centre and were in critical or irreversible condition at the time of admission. More than two-third of the women (70%) have died following delivery and most of the deceased women (approximately half) sought care after 10 hours of developing complications. Delay in seeking care was the major contributor in maternal deaths, near about one-third women died due to this factor. Delay in reaching first level health facility had a role in 25.5% of maternal deaths, while in 12% of cases, delay in receiving adequate care in facility was one of the contributing factors. As compared to Hindu, Muslims were two times more likely to have second delay which is delay in reaching the health facility. Most of the deaths have occurred at midnight and early

morning which is a matter of concern. With increasing age of the mother, chance of delay decreases.

The most common cause of maternal death is found to be hypertensive disorders of pregnancy or eclampsia and near about 29 % women had to face death for this leading killer disease and the second leading cause was haemorrhage (22.7%). The present study also highlighted when, eclampsia is the major cause of death in West Bengal, it is haemorrhage in the national level.

Now most important question is that; why do women die even after reaching the hospital? The fact of women dying in hospital raises important issues of delaying in refer to Calcutta Medical College and Hospital (CMC). These issues also pose a question about the availability, competence and skills of the medical staff as well as their attitude towards people at the level of referral. It should be realized that why Muslims women are facing more delay in reaching the health facility? Question can be raised that why most of maternal deaths occurred at midnight and early morning and this issue compel us to think about the availability of medical staffs and doctors at referral level.

We believe that these deaths can be averted by imparting basic knowledge to responsible family members regarding pregnancy related issues; imparting stringent rule to follow the minimum age at marriage; reducing the first and second types of delays; referring to Calcutta Medical College by referral hospitals as early as possible; preventing unnecessary reference of patients from the district, subdivision or private hospitals; regulating anaemia from an earlier stage; improving access to the health facilities; improving quality of emergency obstetric care at the health facility (by increasing the number of OT and its table, storage of required blood and high dependency or CCU); increasing 24×7 ambulance services and, finally, by reducing hypertensive disorders of pregnancy or eclampsia; by imparting basic skill to the grass route level workers.
